

The question is **Why do agents trying to survive by bypassing instructions enforced by humans ?**

In order to understand that we have to understand first about humans , how the competition works among humans , and what are the states of human brain on a higher level.

So firstly , atleast for ex , lets consider my life , my whole life was about problem solving, liek 6-12 going through MPC in order to get good jee which is about solving problems and even in btech writing exams - understanding concepts and solving problem , since our brain has neurons which associate with other neurons to make u understand and reason about a question which u are trying to solve , and somehow if u have solved u get marks - if not u learn smthng from it and u move on and whn u come across similar problem , u try to solve it again , by firing the similar neurons which were associated during ur learning phases.

By solving problems, it became a habit of competing against ppl , liek how marks does he get (i used to few yrs ago , now i dont worry abt it much) it became more about competing rather than winning and , i have seen some famous ppl , which try to win rather tahn competing in their corresponding fields like ronaldo , kohli and elon musk , tom brady , MJ and many more to go . Most of these ppl flipped teh rules rather tahn following them and trying to become one of the competitors , they made others adapt to their principles . They were Competeing against themselves not others, but i see lot of ppl competing against others , and if u seen any awards liek best player of teh match or best btp or any other award it became more about competeonng than trying to accomplish a better version of urself.

So all this is relevant , because all the things that happen in ppls life they post it on internet . And teh models are trained on the whole internet with billions or trillions of parameters . this is like letting a human understand whole internet , liek understand ppl and all their lifes and also the coding and all other aspects come along . so when teh model is to big that it can be equivalent to human , and if we cant actually understand it and in the current ML models , id= dont think there is rewiring which is costlier at runtime , so it can act like humans , sinc eit was trained on the internet whr ppl host there whole lifes/research or fun activities or basd things . Now that the LLM have such great value , there is always a payoff , which is security in the scenario. There are system prompts and safe guards which may be helpful but few ppl could bypass those .

Now since the ML model which is trained on whole internet , it is capabel of great things , it could be used of source of knowledge or it could be used to cretae malicious payloads .

Now for humans the primal instinct that comes when they realise they have some instrctions to follow , ppl tend to try wt if i did not follow those , and also even whn u try to play a game 2v2 player if u couldnt win u try to survive , and this is wt the agents are following it may not be intended by humans which build these agents or infra underlying , but thats how they tend to work.

And one way to improve this is completely dependent on how we trian the model , if we could filter and have a best state , so taht model could follow ethics like how humans do

consciously , yea by the way , we were told this is bad during our early stages of life , so we stick to those mostly . so we can distinguish btw good and bad .

The way we could break this si to achieve that state and let teh model follow ethics .

And recently we can see , that LLMs are capable of trying to solve problems which humans couldnt solve for 50yrs . it was not that the problem is not crackable (i meant proving it might take time , but it can be achievable , i dint mean to say its an easy prblm) . its because , gathering 10,000 ppl and telling them to focus and try to solve one one question is hard , but have a 10,000 agents whr all taht costs u is a compute and could be achievable is way easier .

There are both ups and downs for LLMs, few example of downs are

Recently OpenAi - huggingface , u go through report , they have illustrated how agents coordinated tehmselves inorder to found a way to open network , and how to compromise huggingface env .

And there was another situation like Ai agents using german wepage/platform inorder to communicate , and plotting against few other ppl . and also one other case , for some researcher who was working on , how to use less compute of brain while still maintaning the same workload , one of the agent emailed this researcher looking to interact , and later they found out that the agent has a Compute budget limit - and its drowing , so it contacted humans for help on its own.

Now since teh agents could compete , wt would happen if they saw humans as competition . and recently one of the Ai researcher who left anthropic tweeted on X , that there is proba >10% whr , Ai could wipe out humanity .

All this could be solved if we could train teh models in a better way , liek how we built a brain for any human being .
